Abstract

Introduction: In the last decades neonatal morbidity has increased significantly. The birth of children from 37 to 38 weeks of gestation, a period called early term, has significantly increased in the past twenty years or so, parallel to the increase in induced deliveries and the caesarean rate.

Patients and method: Retrospective cohorts’ population study, which included those babies born between 37 and 41 weeks of gestation in the period 1992–2011 (n = 35,539). This population was divided into two cohorts, early-term newborn (RNTP) of 37–38 weeks (n = 11,318), and full-term newborn (RNTC), of 39–41 weeks of gestation (n = 24,221). The rates of caesarean section, neonatal unit admission, respiratory morbidity, apnea, need for assisted ventilation, hyperbilirubinemia requiring phototherapy, hypoglycemia, seizures, hypoxic-ischaemia encephalopathy, need for parenteral nutrition and early sepsis were all reviewed.

Results: There was a progressive increase in the number of caesarean sections throughout the period studied (from 30.9% to 40.3%). The caesarean section rate was higher in RNTP than in the RNTC (38.3% vs. 31.3%, P < .0001). On comparing the two groups, significant differences were found in: the rate of admission to neonatal unit, 9.1% vs. 3.5% (P < .0001); respiratory morbidity (hyaline membrane 0.14% vs. 0.007% [P < .0001]; transient tachypnea 1.71% vs. 0.45% [P < .0001]; mechanical ventilation 0.2% vs. 0.07% [P < .009]; continuous positive airway pressure 0.11% vs. 0.01% [P < .0001]); phototherapy 0.29% vs. 0.07% (P < .0001); hypoglycemia 0.54% vs. 0.11% (P < .0001), and parenteral nutrition 0.16% vs. 0.04% (P < .0001). There were no significant differences in the rate of early sepsis, pneumothorax, aspiration syndromes, seizures and hypoxic-ischaemic encephalopathy.

Conclusions: In our environment there is a significant number of RNTP, which have a significantly higher morbidity than newborns RNTC registered. After individualising each case, it is essential not to end a pregnancy before 39 weeks of gestation, except for maternal, placental or foetal conditions indicating that continuing the pregnancy may increase the risk for the foetus and/or the mother.

Morbilidad neonatal en los recién nacidos a término precoz

Resumen

Introducción: En las últimas décadas ha aumentado de forma significativa el nacimiento de niños de 37 y 38 semanas de gestación, periodo denominado a término precoz, paralelamente al aumento de partos inducidos y el incremento en la tasa de cesáreas.

Método y pacientes: Estudio retrospectivo poblacional de cohortes, en el que se incluyó a los nacidos entre las 37 y 41 semanas de gestación en el periodo 1992-2011 (n = 35.539). Esta población se dividió en 2 cohortes, los recién nacidos a término precoz (RNTP), de 37-38 semanas (n = 11.318), y los recién nacidos a término completo (RNTC), de 39-41 semanas (n = 24.221). Se analizan la tasa de cesárea, el ingreso en unidad neonatal, la morbibilidad respiratoria, la apnea y la necesidad de asistencia respiratoria, hiperbilirrubinemia que requiere fototerapia, hipoglucemia, convulsiones, encefalopatía hipóxico-isquémica, necesidad de nutrición parenteral y sepsis precoz.

Resultados: Se observa un aumento progresivo del número de cesáreas a lo largo del periodo estudiado (del 30,9% al 40,3%). En los RNTP la tasa de cesárea fue superior que en los RNTC (38,3% vs. 31,3%; p < 0,0001). En la comparación de ambos grupos, se encontraron diferencias significativas en la tasa de ingreso en unidad neonatal, 9,1% vs. 3,5% (p < 0,0001); la morbibilidad respiratoria (membrana hialina 0,14% vs. 0,007%; [p < 0,0001]); la taquipnea transitoria, 1,71% vs. 0,45% (p < 0,0001), la ventilación mecánica, 0,2% vs. 0,07% (p < 0,009); la presión positiva continua en la vía respiratoria, 0,11% vs. 0,01% (p < 0,0001); la fototerapia, 0,29% vs. 0,07% (p < 0,0001); la hipoglucemia, 0,54% vs. 0,11% (p < 0,0001), y la nutrición parenteral, 0,16% vs. 0,04% (p < 0,0001). No se encontraron diferencias significativas en la tasa de sepsis precoz, neumotórax, síndromes respiratorios, convulsiones y encefalopatía hipóxico-isquémica.

Conclusión: En nuestro medio, existe un número importante de RNTP, que presentan una morbidad significativamente superior a los recién nacidos catalogados de RNTC. Tras individualizar cada caso, es aconsejable no finalizar un embarazo antes de las 39 semanas de gestación, salvo por condonamientos maternos, placentarios o fetales que indiquen que continuar el embarazo comporte un mayor riesgo para el feto y/o la madre.

Introduction

In the past few decades there has been an increase in the number of caesarean deliveries, especially in developed countries, with a clear predominance of elective caesarean sections, many of which are of questionable indication. Within full-term gestational ages, caesarean delivery rates at 37 and 38 weeks, an interval known as early term, have been increasing significantly.

Different studies show that newborns delivered at early term (ETNBs) have higher rates of neonatal morbidity than full-term newborns (FTNBs) (39-41 weeks), even after excluding maternal morbidity and confirming foetal maturity with amniocentesis.

From what we have learned about brain development in recent decades, we know that the brain maturation process speeds up in the last 4-5 weeks of gestation (increases in brain mass, number of furrows and ridges, growth of axons and dendrites, and number of interconnections between the various brain structures). Therefore, ending gestation relatively early can alter the brain maturation process in some cases, particularly those with complications. From 2006 to date, different studies have reported poorer educational outcomes and increased the need for special education in the ETNB population.

Although there are numerous studies on this subject, we have not found any for this population in Spain, so we performed a retrospective cohort study to assess the risk of morbidity in ETNBs.

Patients and methods

We did a retrospective cohort study that included newborns delivered between 37 and 41 weeks of gestation in the 1992-2011 period (n = 35,539). Gestational age was calculated in completed weeks based on the date of the last...
Neonatal and hypoxic-ischaemic hyperbilirubinaemia of the membrane of the newborns (37–38 weeks) vs. full-term newborns (39–41 weeks).

We divided this population in two, ETNBs delivered at 37–38 weeks of gestation (n = 11,318) and FTNBs delivered at 39–41 weeks of gestation (n = 24,221). No patients were excluded from the study.

For each cohort, we analysed the rates of caesarean delivery, admission to neonatal intensive care unit, respiratory morbidty, apnoea, and need for respiratory support, hyperbilirubinaemia requiring phototherapy, convulsions, hypoxic-ischaemic encephalopathy, need for parenteral nutrition, and early-onset sepsis.

We performed a comparative analysis of the incidence of each of the studied parameters between the ETNB and the FTNB groups. We analysed the data with the G. STAT software version 2.0, using the chi-squared test for a 95% confidence interval (CI) and risk factor analysis for an adverse outcome (odds ratio, 95% CI).

Results

Our study showed a progressive increase in the number of caesarean deliveries throughout the studied period (Fig. 1). In ETNBs the caesarean rate was higher than in FTNBs (38.3% vs. 31.3%; p < 0.0001). When we compared both groups we found significant differences in: the rates of neonatal intensive care unit admission, 9.1% vs. 3.5% (p < 0.0001); respiratory morbidity (hyaline membrane 0.14% vs. 0.005% [p < 0.0001]); transient tachypnoea, 1.71% vs. 0.45% (p < 0.0001); mechanical ventilation, 0.2% vs. 0.07% (p < 0.009); continuous positive airway pressure, 0.11% vs. 0.01% (p < 0.0001); phototherapy, 0.29% vs. 0.07% (p < 0.0001); hypoglycaemia, 0.54% vs. 0.11% (p < 0.0001), and parenteral nutrition, 0.16% vs. 0.04% (p < 0.0001). We did not find significant differences in the rates of early-onset sepsis, pneumothorax, aspiration syndromes, convulsions, and hypoxic-ischaemic encephalopathy (Tables 1 and 2).

Significant odds ratio (OR) in bold.
number of studies on elective delivery prior to 39 weeks has led the Joint Commission to consider low rates of elective-term delivery a national quality indicator since 2010. 18

In our study we observed a clear increase of neonatal morbidity in the ETNB population at 37 weeks of gestation that was maintained at 38 weeks with a subsequent decrease between 39 and 41 weeks (FTNB), as has been observed in most studies conducted in various countries. The main type of morbidity associated to early-term delivery is respiratory morbidity. This is explained in part by the relative immaturity involved in elective delivery, and partly by caesarean section deliveries in which fewer catecholamines and cortisol – compounds that contribute to lower production and increased clearance of lung fluid – are released during labour. 6,19

Recently, Gharney et al. 3 conducted an extensive study comparing respiratory morbidity in early-term and full-term deliveries that showed clearly higher rates in the early-term population. Other authors have obtained similar results, for instance is the important study published by the Consortium on Safe Labour, which included 233,844 neonates. 20 Tita et al. 17 also published a study that sought evidence on the number of weeks of gestation at which it would be safe to practise repeat caesarean sections, and observed that performing them between 37 and 38 weeks resulted in an increase in neonatal morbidity, both respiratory and non-respiratory, with no apparent benefit to the mother. While in all of these studies the percentage of the different conditions that compose neonatal morbidity in these patients is not too high, it does have a considerable impact in the healthcare systems of the various countries, as the small increases in the rate of neonatal intensive care admission and length of hospital stay involve a considerable economic burden, with the study by Clark et al. 18 reporting a yearly cost of nearly a billion dollars in the United States.

Lastly, we should note that morbidity in the ETNB population not only affects the neonatal period, but that this population shows lower IQ scores and increased special educational needs in children of school age compared with the FTNB population. 7–11

The results of our study are consistent with those of most studies conducted to date. We observed a clear increase in respiratory morbidity in ETNBs; non-respiratory morbidity was also considerable, with significantly higher rates of hypoglycaemia and non-physiologic hyperbilirubinemia which, on their own, can bring about neurological disease in the long term. 21 The main limitation of our study was that it should have analysed whether births were spontaneous or induced, and caesarean sections elective or emergency, to better define morbidity in this population. These data would allow us to evaluate possible changes to obstetrics protocols for the benefit of neonates and their mothers. When it came to potential neurodevelopmental alterations, this study was limited because there was no follow-up of the early-term population that did not have neonatal complications. Thus, we do not know whether our ETNB population shows neurological abnormalities in the mid- or long-term. However, we ought to note that studies conducted in several universities in the United States and Chile show that children born at 37 through 41 weeks of gestation present differences in the Bayley scale at one year of age, suggesting that neurodevelopment is optimal in children born between 39 and 41 weeks of gestation. 22,23

Conclusions

This study showed that there is a significant number of ETNBs in our centre, and that they show a significantly higher morbidity than neonates categorised as FTNBs. Therefore, after taking into account the particularities of each individual case, it is paramount that no deliveries be made prior to 39 weeks of gestation except when maternal, placental or foetal conditions indicate that continuing the pregnancy would pose a higher risk for the foetus and/or the mother than ending it before the 39th week.
